

Comparative Analysis of Phenotypes: Participants with Long COVID vs. Post-Vaccination Syndrome in the LISTEN study

October 19, 2023

Yale SCHOOL OF MEDICINE

Background

Long COVID (LC)

- Numerous studies have characterized long COVID, and published criteria for this condition exist.¹
- There is a need to determine how published criteria for long COVID performs in a self-selected group of people reporting long COVID.

Post-Vaccination Syndrome (PVS)

- Adverse events following vaccination have been reported by the CDC.²
- A less well-characterized adverse event is a chronic syndrome with symptoms that begin soon after vaccination.³

What are the similarities and differences among LISTEN participants with either long COVID or post-vaccination syndrome?

Methods

Definitions

Long COVID (LC)

- Defined by self-reported response to the question “Do you think you have long COVID (symptoms that persist at least 4 weeks after infection)?”

Post-Vaccination Syndrome (PVS)

- Synonymous to vaccine injury (VI)
- Defined by self-reported response to the question “Do you think that you were injured by the vaccine?”

Methods

Bivariate Analysis

- Variables
 - Demographic and socioeconomic details
 - Pre-pandemic comorbidities
 - New-onset conditions
 - Infection characteristics
 - Vaccination history
 - Health status
 - Symptomatology and treatment experiences

Clustering and Machine Learning Model

- gradient-boosted tree machine with 5-fold 5-repeat cross-validation
- K-means clustering

Variables

- symptoms

Results

Results - Demographics, socioeconomic characteristics

Long COVID (LC)

- Median age was 46 years, 74% female, 86% white.

Post-Vaccination Syndrome (PVS)

- Median age is 46 years, 80% female, 87% white.

No significant differences in

- Age, race and ethnicity
- marital status, pre-pandemic employment status, or pre-pandemic household income

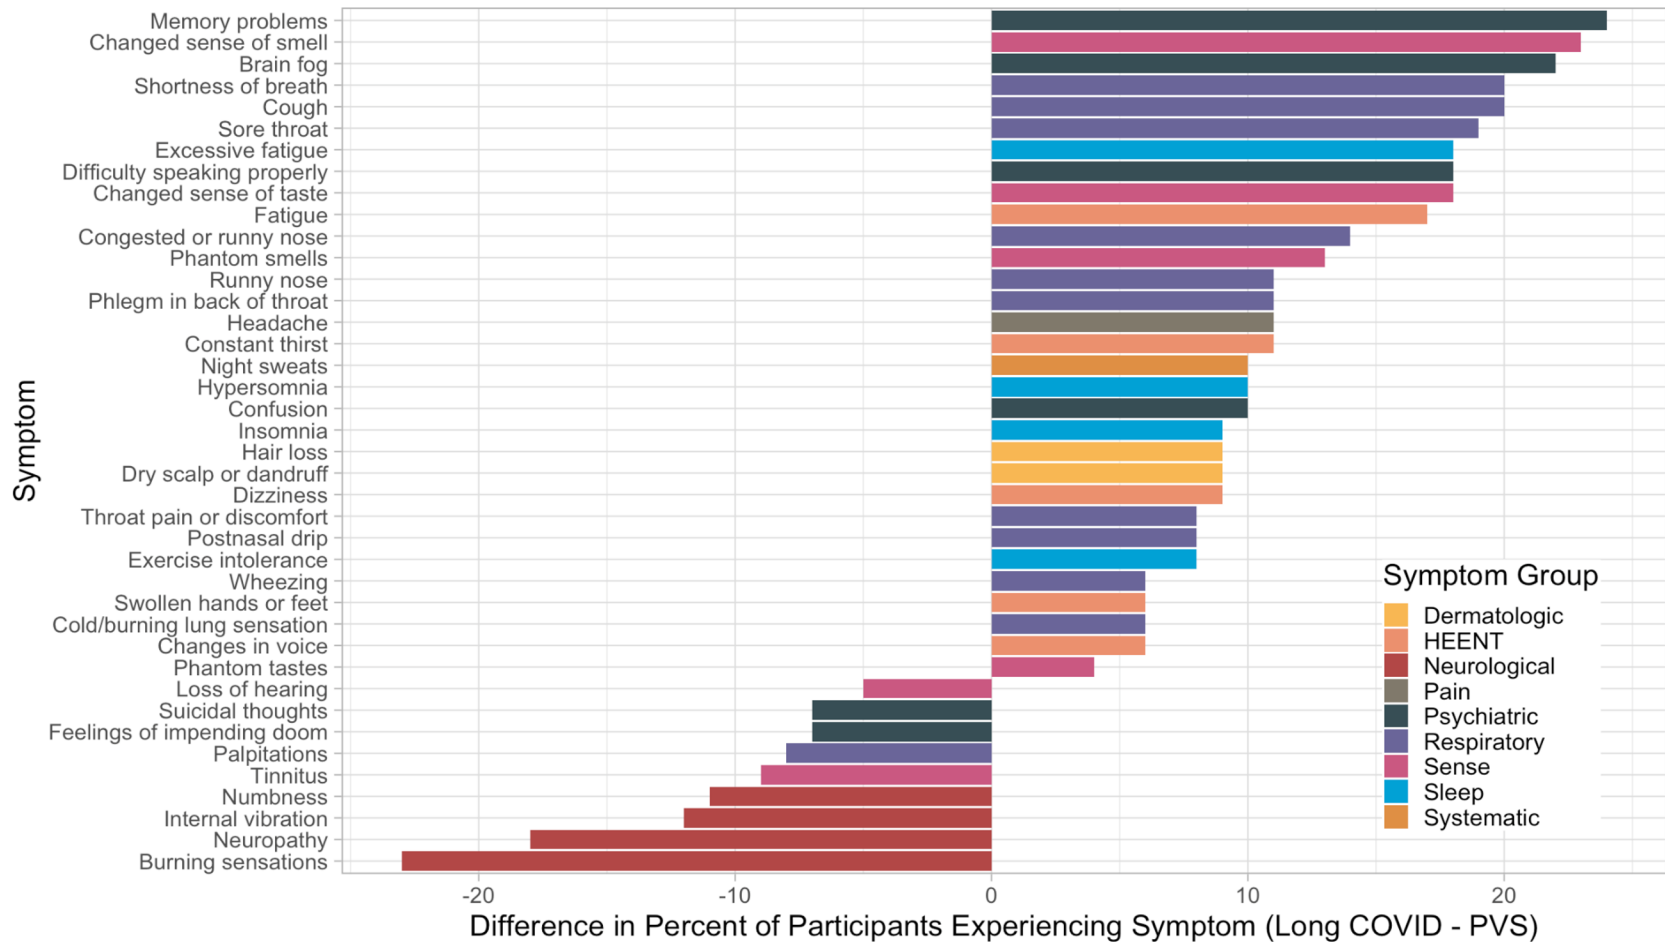

Results

Pre-pandemic comorbidities

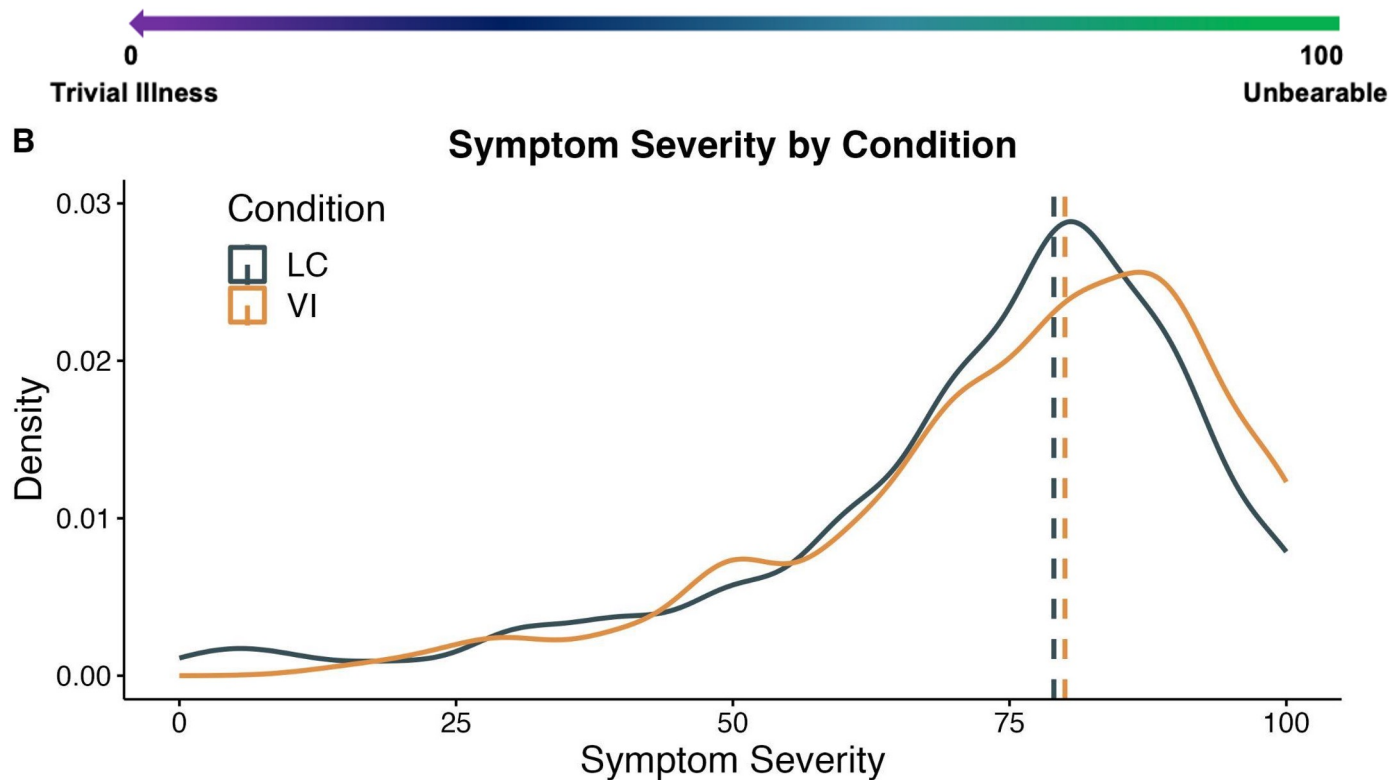

- Participants with long covid were more likely to have chronic lung disease (5% vs 2%) ,ME/CFS (19% vs 12%), depressive disorders (28% vs 20%).
- Participants with PVS were more likely to have cerebrovascular conditions affecting blood vessels to or in the brain (including stroke) (5% vs 2%), MCAS (12% vs 7%), neurological conditions (33% vs 16%).

New-onset conditions

- Participants with long covid were more likely to have: depressive disorders (29% vs 20%), bipolar and related disorders (3% vs. 0.4%).

Results – Symptom Severity

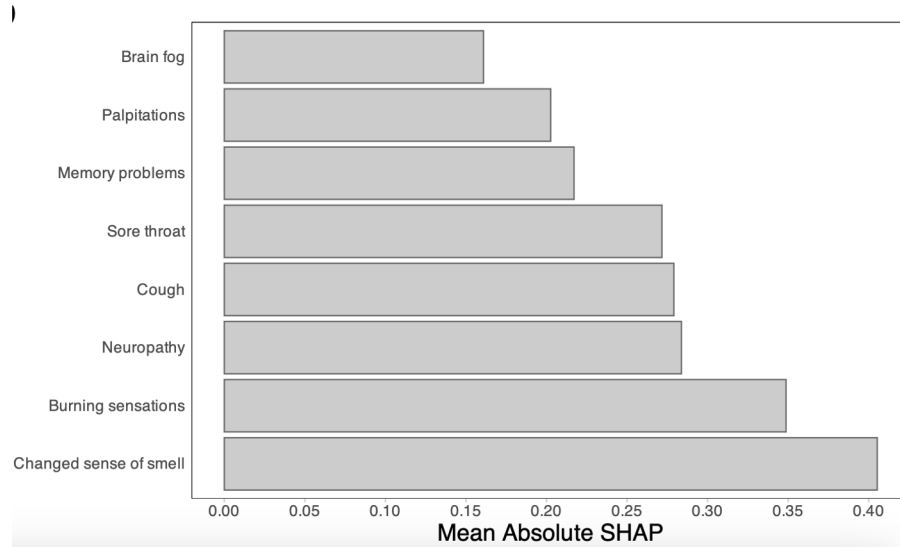

Results - Health status

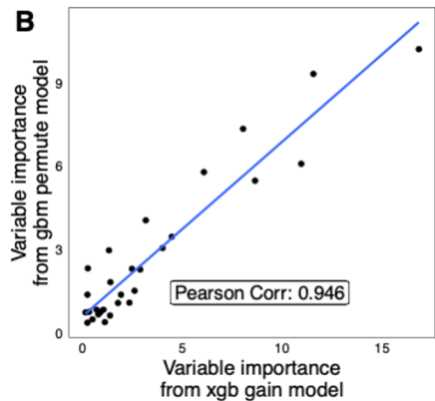

Treatments

Differentiating LC from PVS Participants With a Machine Learning Model

Comparing ML Models

Symptom Clustering

Implications

1. LISTEN participants with either LC or PVS have similar demographic characteristics
2. Both groups reported numerous symptoms and overall poor health status
3. The most important symptoms that differentiate the groups seem to be brain fog, changed sense of smell, cough, and burning sensations
4. The clustering analysis reveals three clusters, where one has a relatively higher proportion of people with vaccine-associated symptoms. This may suggest that the mechanisms for the two conditions are distinct.
